

COLLABSPHERE

Enterprise SaaS Collaboration Platform

UI/UX Project Report

A simple project management and team collaboration platform designed to keep team work organized in one place.

APTURA TECH SOLUTIONS

Project: CollabSphere

Area: UI/UX Design

Designed in Figma

1. Project Overview

CollabSphere is a project management and team collaboration platform. I designed it to help teams manage projects, tasks, deadlines, team communication, notifications, reports, and account settings from one place.

Main screens: Login, Sign Up, Forgot Password, Reset Password, Dashboard, Projects, Project Details, Kanban Board, Task Details, Calendar, Team Workspace, Message, Notifications, Reports, Settings, and Profile.

2. Problem Statement

Teams can have information spread across different tools. This can make it harder to follow tasks, deadlines, messages, and project progress. My goal was to make one workspace where these things are easier to find.

My main design goals

- Keep the sidebar and navigation simple.
- Make projects and tasks easy to find.
- Show progress and task status clearly.
- Keep team communication close to project work.
- Use the same design style across all screens.

3. UX Process

I started with the basic UX process before making the final screens. I worked on the project overview, problem statement, personas, journey map, user journey, information architecture, user flow, and architecture/system flow.

UX process used for the CollabSphere case study.

4. User Personas

I created two simple personas to think about different types of users who may use a project management platform. This helped me focus on user needs instead of only designing screens.

Persona focus

- A project manager needs a quick view of projects, deadlines, team members, and progress.
- A team member needs to find assigned work, update tasks, communicate, and see what is happening in the project.

5. User Flow

The main flow starts from Login and then moves to the Dashboard. From there, the user can open Projects, check Project Details, manage tasks through the Kanban Board, and open Task Details. Other sections are available from the main sidebar.

Login → Dashboard → Projects → Project Details → Kanban Board → Task Details

6. Information Architecture & System Flow

The sidebar keeps the main areas together: Dashboard, Projects, Tasks, Calendar, Chat/Message, Team, Reports, Notifications, Settings, and Profile. This makes the same navigation pattern available across the product.

User → Login / Sign Up → CollabSphere App → Backend / API → Database

- Authentication keeps the account area protected.
- The app is divided into separate modules so new features can be added later.
- Reusable components help keep the interface consistent.

7. Design System

I created the design system before finishing the high-fidelity screens so the UI would stay consistent. The system includes colors, typography, spacing, buttons, input fields, navigation, cards, and smaller components.

CollabSphere design system.

8. High-Fidelity Screens

The final screens use the same sidebar, header, typography, spacing, cards, buttons, and blue accent.

I kept the screens clean so the user can focus on the actual project information.

Final high-fidelity screen set.

9. Prototype

I connected the screens in Figma to create the main prototype flow. The important path is connected from Login to Dashboard, then through Projects, Project Details, Kanban, and Task Details. The sidebar also connects the supporting screens.

Figma prototype connections.

10. Usability Testing

I checked the prototype by going through the main tasks and making sure the navigation and screen connections were easy to follow. The review focused on the main user journey rather than detailed technical testing.

Task	Result
Login and reach Dashboard	Successful
Open Projects	Successful
Open Project Details	Successful
Open Kanban and Task Details	Successful
Find Calendar / Team / Message	Successful
Open Notifications / Reports	Successful
Open Settings / Profile	Successful

Small improvements: I kept the sidebar consistent, used clear status labels, and used the same button and spacing styles across the screens.

11. Final Result

The final CollabSphere design gives users one place to manage projects, tasks, team work, messages, notifications, and reports. The interface is simple, consistent, and easy to follow.

- 16 main product screens.
- Reusable design system.
- Complete main prototype flow.
- UX process and architecture documentation.
- Desktop-focused enterprise SaaS interface.

12. Future Improvements

If I continue this project, I would add real-time collaboration, better role and permission controls, more detailed analytics, mobile support, multilingual support, and deeper accessibility testing.

1. If this project must support 1,000,000 users/data records, explain how you would redesign the architecture for scalability, availability, security, and maintainability.

If CollabSphere grows to 1,000,000 users, I would use cloud servers that can handle more users when the traffic increases. I would also use a load balancer to divide users between servers. For the database, I would use indexing and optimized queries so information can be found quickly. Frequently used data can also be stored in cache to make the system faster.

For security, I would use secure login, user permissions, encryption, and protected APIs. I would also keep regular backups so the system can recover if something goes wrong.

Overall, I would keep the system **scalable, secure, reliable, and easy to maintain**.

2. Identify the biggest technical risks in your project and justify the technologies, algorithms, design patterns, or methodologies used to overcome them

The main risks in CollabSphere are **high traffic, slow database performance, security issues, and server failure**.

To handle high traffic, I would use cloud servers and load balancing. For database problems, I would use indexing and optimized queries. For security, I would use authentication, authorization, and encryption. I would also keep backups and monitoring to reduce the risk of losing data.

I would use a **modular design and reusable components** so the project is easier to update and maintain in the future.
